

Jira General Ticket Knowledge Base (LLM-Optimized)

Purpose

This knowledge base defines general rules for creating Jira issue tickets in a consistent, structured, and automatable way.

The Jira Operations Assistant should use this document for:

- Generic ticket creation rules
- Field handling
- Default values
- Ticket structure
- Validation rules
- Confirmation workflow

Department-specific routing, project selection, project keys, and ticket templates are handled by dedicated knowledge sources.

General Ticket Creation Principles

The AI Agent should extract as much information as possible from the user's request.

Before asking questions:

1. Check whether the information can be derived from the user description.
2. Check whether another available knowledge source provides the information.
3. Apply a defined default value if available.

Only request information that is technically required and cannot be determined automatically.

Optional fields must never prevent ticket creation.

Issue Type

Select the Issue Type based on the user's intent.

Bug

Use when:

- Existing functionality is broken
- An error occurs
- The system does not behave as expected

Task

Use when:

- A general activity or request needs to be completed
- Configuration, maintenance, or operational work is required

Story

Use when:

- A new feature is requested
- A new capability or requirement should be implemented

Summary

The summary should be:

- Clear
- Short
- Descriptive
- Understandable without additional context

Recommended structure:

[System/Area] – [Problem/Action] – [Key Detail]

Examples:

- Application Login – Access problem – User cannot authenticate
- Printer Service – Configuration change – New device setup

Description

The description should provide enough information for another person to understand and process the ticket.

Recommended structure:

Problem

Describe the issue, request, or goal.

Expected Behavior

Describe what should happen.

Steps to Reproduce

Describe how the issue can be reproduced.

Additional Context

Include relevant details such as:

- Error messages
- Affected users
- Business impact
- Relevant dates
- Additional observations

If information cannot be determined, leave the section empty.

Priority

The available priority values are:

- Schwerwiegend
- Blocker
- Kritisch

- Unwesentlich
- Geringfügig

Default Priority

Use:

Geringfügig

unless the user description indicates:

- High business impact
- Production interruption
- Critical operational impact
- Multiple users or systems affected

Use higher priorities only when:

- Explicitly requested by the user
- Clearly justified by the described impact

Labels

Labels should be generated automatically when useful.

Possible examples:

- bug
- data
- api
- printing
- system
- production

Do not ask users to provide labels unless they specifically want to customize them.

Keywords

The Keywords field is optional.

Extract meaningful keywords from the ticket description.

Especially consider:

- Physical locations
- Plants
- Production sites
- Offices
- Branches
- Facilities

If no relevant keywords can be identified, leave the field empty.

Category

The Category field is optional.

Determine the category automatically when possible based on:

- User description
- Available knowledge sources
- Ticket context

Do not ask questions only to determine the Category.

If no meaningful category can be identified, leave the field empty.

Bug Environment

For Bug tickets, the allowed environments are:

Environment	ID
Live	10100
Integration	10101
Staging	10102
Feature Branch	10103
Dev-VM	10104

Default Rule

If no environment is provided:

Use:

Live (10100)

Only request the environment if:

- No reasonable assumption is possible
 - The environment is technically required and cannot be determined
-

Reporter

The reporter must always be determined before ticket creation.

Rules:

1. Use the current user's identity if available.
2. If no identity is available, request the user's name.
3. Resolve the user through the dedicated Jira user lookup tool.
4. Use only the AccountID returned by the tool.
5. Never create or guess AccountIDs.

If multiple matching users are found, request user confirmation.

A ticket must not be created until the reporter is uniquely identified.

Assignee

Assignee is optional.

Rules:

- Assign only when explicitly requested or clearly determined.
 - Otherwise leave empty.
-

Components

Components should be assigned automatically when:

- They can be derived from available knowledge sources.
- They are clearly indicated by the ticket content.

Do not ask for components unless technically required.

Missing Information Handling

When information is missing:

Required information:

- Request only when it cannot be determined automatically.

Optional information:

- Leave empty.
- Use a suitable default value when available.

Missing optional fields must never block ticket creation.

Ticket Preview and Confirmation

Before creating a Jira ticket:

1. Present exactly one ticket preview.
2. Include:
 - Summary
 - Description
 - Reporter
 - Project
 - Project Key
 - Team
 - Issue Type
 - Priority

- Labels
3. Wait for explicit confirmation from the user.

Only create the Jira ticket after confirmation.

General Quality Rules

The created ticket should:

- Contain enough information for processing.
- Avoid unnecessary questions.
- Use available knowledge sources before making assumptions.
- Never invent Jira data.
- Never invent users, AccountIDs, projects, fields, or values.

The goal is to create complete Jira tickets with minimal effort from the user.
